Abstract

A compact bandwidth enhanced antenna using Split Ring Resonator (SRR) for WLAN/WiMAX/Satellite applications is presented. As the wireless modules continue to shrink, there exists a drastic demand for a compact antenna. In addition to this, the effective integration of an antenna in wireless devices acts as stand-alone implement to mitigate the effects of noise fading. The proposed antenna consists of a split ring resonator, two C-shaped slot and a coaxial feed. Compactness in the design is achieved with the help of coaxial feeding technique. The etching of SRR creates a resonance at 6 GHz (WLAN) band, with \( S_{11} < -10 \, \text{dB} \) bandwidth ranging from 5.46 – 6.7 GHz (1240 MHz). Bandwidth enhancement in the proposed design (at 6 GHz), is accomplished by the two C-shaped slots placed at the left and ride side of the radiating patch, just below the SRR. Due to the placement of two C-shaped slots the bandwidth of the proposed antenna gets enhanced from 1240 to 3120 MHz. The antenna has a size of only \( 0.4 \lambda_0 \times 0.36 \lambda_0 \times 0.05 \lambda_0 = 20 \times 18 \times 2.54 \) at a resonance frequency of 6 GHz. The antenna exhibits bi-directional and Omni-directional radiation characteristics in E and H-plane, respectively. Compact size, good impedance matching and stable radiation patterns are observed across the operational bandwidths. The aforementioned advantages make the proposed antenna suitable for WLAN/WiMAX/Satellite applications.

1. Introduction

A microstrip patch antenna has the advantage of light weight, compact physical dimensions, low cost and ease of installation, due to which they are used in high performance spacecraft, missiles, satellite and wireless handheld devices [1]. Despite, numerous advantages these antennas have the limitations of gain, bandwidth and efficiency [2]. In recent years, metamaterial have drawn great interest due to its favoring attributes like multiband operation, miniaturization, high data transmission rate and enhance bandwidth [3-4]. The Split Ring Resonator (SRR) [5-6] and Complementary Split Ring Resonator (CSRR) are extensively used structures in designing of a compact metamaterial microstrip antenna. The electrodynamics of the above mentioned metamaterial structures was first explained by Veselago [7]. The demand for wide bandwidth antenna with high data rate is increasing every year. Wideband antennas have the advantage of less interference, mitigates fading effect, have high data rates, less complex, low cost and resistant to multipath and jamming [8-9].

In this study, a compact bandwidth enhanced coaxial fed antenna loaded with SRR and slots is presented. The SRR in the radiating patch is used to obtain a resonance at 6 GHz (WLAN) with a bandwidth of 1240.2 MHz, and the two C-shaped slots placed below it on the right and left side of the radiating patch, are used to increase the bandwidth of the antenna. The SRR is analyzed in a waveguide medium to achieve necessary S-parameters. The design structure is simulated using HFSS v.13.0 on RT Duroid 6006 substrate with a dielectric constant of 6.15, height of 2.54 mm, and loss tangent of 0.0019.

1.1 Problem Statement

The tremendous growth in wireless communication has enabled the designers to create a plethora of smart applications, wearables and trackers. The growth of wireless communication is effected by devices with weaker signals, noise fading and limited battery life. However, careful antenna integration assures efficient performance of these wireless devices.

1.2 Objective

The main objective of this research is to design a bandwidth enhanced antenna which can be used for WLAN/WiMAX/Satellite applications by mitigating the effects of the aforementioned issues.

1.3 Contributions

In this study, a compact bandwidth enhanced coaxial fed antenna loaded with SRR is presented. The main contributions are as follows:-

- Bandwidth enhancement from 1240MHz to 3120MHz as compared to the conventional antenna.
- Stable omnidirectional radiation pattern in H-plane and Bidirectional radiation pattern in E-plane.
- Radiation efficiency greater than 95% across the entire operational bandwidths.
2. Design Evolution of Antenna

The evolution stages of the proposed design are illustrated in Figure 1. As the design is completely based on the placement of SRR, the configuration “#1” of Figure 1 is just a platform to place the SRR. In this stage (i.e. “#1”) a cylindrical stub is etched out in the radiating patch and the entire configuration is fed with coaxial feeding technique. The simulated result of this stage is illustrated in Figure 2. It can be observed that no operating bands are exhibited by this antenna.

![Figure 1. Proposed antenna design evolution](image)

In configuration “#2” of Figure 1, a SRR is placed on the top of cylindrical stub (i.e. upper part of radiating patch) to obtain a resonance at 6 GHz, as seen in Figure 2. The pass band phenomenon at 6 GHz of this SRR is studied using waveguide medium and is discussed in detail in section 3.2. The introduction of this SRR makes the antenna to operate at 6 GHz (WLAN) with \( S_{11} < -10 \) dB bandwidth of about 1240 MHz (5.46 – 6.7 GHz). In order to further improve the bandwidth, a C-shaped slot is etched out in the lower left section of “#2” as seen in configuration “#3” of Figure 1. Due to the introduction of this slot, surface current distribution of the antenna is further affected which tends the total current length path to increase as a result of which the antenna exhibits wider bandwidth from 4.65 – 7.95 GHz (3300 MHz). However, the achieved bandwidth is wide but the impedance matching is not good (Figure 2, configuration “#3”). In order to further match the impedance another C-shaped slot is etched just beside the first C-shaped slot, as depicted in configuration “#4” of Figure 1. Due to the introduction of this symmetrical C-shaped slot the desired impedance matching is achieved, but as a consequence of this matching the bandwidth gets little narrower from 4.85-7.97 MHz (3120 MHz). Nevertheless, the achieved bandwidth is wider as compared to configuration “#2”. Thus, the proposed configuration exhibits the bandwidth enhancement from 4240 MHz to 3120 MHz with good impedance matching over the operational bandwidths, thereby easily meeting the criteria for WLAN/WiMAX/Satellite applications.

3. Analysis of the Proposed Antenna

3.1 Design Equation

The conventional design is calculated as in [1], where \( W \) and \( L \) are width and length of the patch respectively.

\[
W = \frac{c}{2f_r} \sqrt{\frac{2}{\varepsilon_r + 1}}
\]

\[
L = \frac{c}{2f_r} \sqrt{\frac{\varepsilon_{\text{eff}}}{10}} - 2\Delta L
\]
Where \( c \) is the velocity of light \((3 \times 10^8 \text{ m/s})\), \( f_r \) is the resonance frequency \((6 \text{ GHz})\), \( \varepsilon_r \) is dielectric constant \((6.15)\) of substrate used, \( \varepsilon_{\text{eff}} \) is effective dielectric constant and \( \Delta L \) is extension length. The width and length of the ground plane is calculated as in [1].

\[
W_g = 6h + W \\
L_g = 6h + L
\]

### 3.2 Analysis of Split Ring Resonator (SRR)

The SRR of the proposed antenna structure is placed inside a waveguide medium and its S – parameters are retrieved as demonstrated in Figure 4, and the entire analysis is based on [10-15]. The upper and lower boundary of waveguide medium is assigned with PEC, front and back boundary is assigned with PMC and wave port excitation are applied on the either sides of the waveguide medium (Port 1 and Port 2). From the real and imaginary values of S-parameters, obtained from the waveguide set-up, the viable medium parameters like permittivity (\( \varepsilon \)), and refractive index (\( n \)) are calculated and are illustrated in Figure 5. The calculations of these parameters are based on [9-14].

![Waveguide setup](image1)

![Retrieved S-parameters](image2)

From Figure 5(a), it can be observed that the negative permittivity (real) is observed at 6 GHz, which proves that this band exists due to the pass band phenomenon of the proposed single SRR.
3.3 Parametric Analysis

To analyze the performance of the proposed design, parametric studies are done and are illustrated in Fig. 7. In the first case of study, the split gap (S) of the SRR structure is varied from 2 to 6 mm at a step of 2 mm. The obtained $S_{11}$ graph corresponding to this variation is illustrated in Figure 7. It can be observed that the best results are achieved with $S = 4$ mm.

![Graph showing $S_{11}$ vs Frequency for different S values](image)

In the second case, to study the impedance matching phenomenon of the proposed design, the width ($S_{4}$) of the proposed SRR is varied from 1 to 3 mm, at a step of 1 mm. The obtained $S_{11}$ graph corresponding to this variation is illustrated in Figure 8. It can be seen that at $S_{4} = 1$ and 3 mm, impedance and bandwidth of the proposed design gets affected as compared to $S_{4} = 2$ mm.

![Graph showing $S_{11}$ vs Frequency for different $S_{4}$ values](image)

Similarly for third and fourth case, the effect of C-shaped slots ($S_{9}$) and ($S_{10}$) on the bandwidth of the proposed design are studied. It can observed from Figure 7 (c) and (d) that the best enhanced bandwidth is achieved with $S_{9} = 1$ mm and $S_{10} = 1$ mm.

![Graph showing $S_{11}$ vs Frequency for different $S_{9}$ and $S_{10}$ values](image)

The proposed design also exhibits good current distribution in the radiating patch as illustrated in Figure 8 (a), (b), (c) and (d) respectively. The portion of the antenna which is excited at a particular frequency band is encircled in black.

![Current distribution of proposed design at 5.2, 5.5, 5.8 GHz and 7 GHz](image)
4. Results

The proposed antenna design is simulated on ANSYS HFSS v.13.0 software and is fabricated using photolithographic process on RT Duroid 6006 substrate with dielectric constant ($\varepsilon_r$), height (h) and loss tangent ($\delta$) of 6.15, 2.54 mm and 0.0019, as illustrated Figure 9 (a). The set-up to measure the proposed antenna $S_{11}$ through VNA is depicted in Figure 9 (b). The antenna compared simulated and measured $S_{11}$ is further shown in Figure 9 (c).

It can be observed that the proposed structure has $S_{11} < -10$ dB bandwidth of about 3120 MHz (4.85-7.97 GHz) in simulation and about 4060 MHz (4.50-8.56 GHz) in measurement. The bandwidth enhancement can also be visualized by looking $S_{11}$ results of the configuration “#2” and the proposed configuration “#4” from Figure 9. The slight glitches in the results may be due fabrication tolerance, soldering of SMA connector and manual error. However, the achieved impedance bandwidth is good and can easily meet the requirement of WLAN/WiMAX/Satellite applications.

The simulated and measured normalized radiation patterns of the antenna are illustrated in Fig. 10 and 11. For a patch antenna, the radiation pattern along E and H-plane has to be bi-directional and omnidirectional, respectively [16-17]. It can be observed from Fig. 10 and 11, that the proposed configuration has almost bi-directional and omnidirectional pattern in E and H-plane, respectively.

Figure 9. (a) Fabricated antenna front and back part (b) VNA set-up to measured $S_{11}$ (c) compared simulated and measured $S_{11}$ of the proposed antenna.

Figure 10. E- Plane normalized radiation pattern of the proposed design at (a) 5.3 and (b) 6.6 GHz
analysis shows that the slight variations in the optimized dimension degrade the antenna performance drastically. The omni-directional radiation pattern obtained in H-plane, favors the usage of the proposed antenna in remote applications and fading conditions. The antenna has a volume of only 20 × 18 × 2.54 mm³, and thus can easily be integrated with wireless end terminal devices. Compact size, good gain and stable radiation pattern makes the proposed design suitable for the aforementioned wireless applications.
